Today’s Lecture

- Terminology and classification
- Causes of Faults and Trends
- Fault Modeling
  - Hardware
  - Software
Faults

- **Fault**: incorrect state of hardware or software resulting from physical defect, design flaw, or operator error

  - Faults introduced during system design
    - Pentium’s incorrect floating point division design
    - Bug in software could cause infinite loop

  - Faults introduced during manufacturing
    - Bad solder connection between chip pin and motherboard
    - Broken wire within chip

  - Faults that occur during operation
    - Cosmic ray knocks charge off DRAM cell
    - System administrator incorrectly installs new software

Errors

- **Error**: manifestation of a fault
  
  - Bit in main memory is a 0 instead of a 1 (due to cosmic ray)
  - Software pointer that mistakenly points to NULL (due to bug)

  - But not all faults lead to errors!
    - Trees falling in empty forests don’t make sounds

  - Examples of **masked** faults
    - Cosmic ray knocks charge off logic signal, but after it had been correctly latched in and saved
    - Buggy software that isn’t reached
Failures

- **Failure**: system level effect of an error (user-visible)
  - System produces incorrect result of computation (e.g., 2+2=5)
  - System “hangs” (e.g., Blue Screen of Death)
- Not all errors lead to failures!
- Examples of masked errors
  - Bit flip in memory location that’s not accessed again
  - NULL pointer that’s not referenced again

Physical Failures During Lifetime

- Three phases of system lifetime
  - Infant mortality
  - Normal lifetime
  - Wear-out period
- Physical failures follow famous “bathtub curve”

![Bathtub curve graph]

- Infant Mortality: 1-20 weeks
- Normal Lifetime: 7-15 years
- Wearout Period: 7-15 years
**Fundamental Chain of Dependability**

... \(\xrightarrow{\text{fault activation}}\) error \(\xrightarrow{\text{propagation}}\) failure \(\xrightarrow{\text{fault}}\) ...

- **Example 1**
  - A short in an integrated circuit is a failure (with respect to the function of the circuit)
  - The consequence (e.g., stuck at a Boolean value) is a fault that stays dormant until activated
  - Upon activation (invoking the faulty component by applying an input) the fault becomes active and produces an error
  - If and when the propagated error affects the delivered service (e.g., information content), a failure occurs

- **Example 2**
  - The result of an error by a programmer leads to a failure to write the correct instruction or data
  - This results in a dormant fault in the written software (e.g., faulty instruction)
  - Upon activation the fault become active and produces an error
  - When the error affects the delivered service, a failure occurs

- **Example 3**
  - An inappropriate human-system interaction performed by an operator is an external fault (from the system view point)
  - Resulting altered processed data is an error, ……
Fundamental Chain of Dependability

Example 4
- Cosmic ray knocks charge off of DRAM cell
  - Error: bit flip in memory
  - Failure: computation produces incorrect result

Example 5
- Software bug could allow for NULL pointer
  - Bug gets exercised and we get NULL pointer
  - Program seg faults when it tries to access pointer

Propagation and Masking

Impact of faults can spread throughout the system
- If a chip shorts power to ground, it may cause nearby chips to fail as well
- Common clock and power net
- Independence of modules is a strong simplification

Error propagation: Erroneous results used in subsequent computations
- Containment upon detection important

Masking
- Electrical, logical, temporal, behavioral
Masking

- **Logical**
  - E.g., if a fault flips a bit from 0 to 1 and it is then ANDed with a bit that is 0, then the fault cannot manifest itself as an error

- **Functional**
  - E.g., incorrect data is produced by an instruction that gets squashed due to a branch misprediction
  - E.g., the destination register of a NOP is corrupted by a fault

Faults, Errors, and Failures

- **Faults**
  - Permanent (hard) faults
    - Natural failures
    - Natural radiation
    - HW design errors
    - Transient (soft) faults
    - Power transients
    - Switching transients
    - Natural radiation
    - Single upsets
    - Multiple upsets
  - Intermittent faults
    - Natural failures
    - Power transients
    - Software faults
    - SW design errors
    - System upgrades
    - Requirements changes
    - External faults

- **Errors**
  - Failure to meet requirements
    - Reliability, long term
      - Mission life
    - Reliability, short term
      - Critical functions
      - Database protection
    - Availability
    - Detection latencies
    - Containment boundaries
    - Recovery latencies
    - Autonomy

- **Failures**
  - Processor
Reliable Computing I – Lecture 3

Origin of Defects in Objects

- (hardware or software)

- Good object wearing out with age
  - Hardware (software can age too)
  - Incorrect maintenance/operation
- Good object, unforeseen hostile environment
  - Environmental fault
- Marginal object: occasionally fails in target environment
  - Tight design/bad inputs
  - Implementation mistakes
  - Specification mistakes

Fault Classes: Temporal persistence

- **Permanent** faults, whose presence is continuous and stable.
  - E.g., Broken connection → always open circuit
- **Intermittent** faults, whose presence is only occasional due to unstable hardware or varying hardware and software states (e.g., as a function of load or activity)
  - E.g., Loose connection → occasionally open circuit
  - E.g., Bug in little-used software for rounding → incorrect data
- **Transient** faults, resulting from temporary environmental conditions.
  - E.g., Cosmic ray knocks charge off transistor → bit flip
  - Tend to be due to transient physical phenomena
  - Also known as Single Event Upset (SEU)
Fault Classes

- Based on the origin
  - Physical faults
    - Stemming from physical phenomena internal to the system,
    - such as threshold change, shorts, opens, etc.,
    - or from external changes,
    - such as environmental, electromagnetic, vibration, etc.
  - Human-made faults
    - Design faults,
    - introduced during system design, modification, or establishment of operating procedures,
    - Interaction faults,
    - violation of operating or maintenance procedures

Physical Defects: Transient Phenomena

- Cosmic radiation
  - High energy particles that constantly bombard Earth
  - May have enough energy to disrupt charge on transistor (Qcrit)
  - Used to be only a problem for DRAM, but becoming a problem for SRAM and even for logic (as Qcrit decreases)
Physical Defects: Transient Phenomena

- Cosmic radiation trends:
  - $Q_{\text{crit}}$ decreasing
  - Probability increasing that a cosmic ray that hits a transistor will disrupt its charge
  - Transistor size decreasing → smaller probability that a cosmic ray will hit a particular transistor
  - More transistors per system → greater probability of fault

Physical Defects: Transient Phenomena

- Alpha particle radiation
  - Similar to cosmic rays, but radiation comes from metal decay
  - Often, the metal housing of the computer is the source
  - Lead solder joints also a problem → want to use "old lead"
  - Trends (same as for cosmic radiation):
Reliable Computing I – Lecture 3

Physical Defects: Transient Phenomena

- Electromagnetic Interference (EMI)
  - Electromagnetic waves from other sources (e.g., microwave oven, power lines, etc.) can cause transient disruptions
  - EMI can be created by the circuit itself! Called “crosstalk”
  - EMI can induce electrical current on wires and thus change the signals on wires
- There are other sources of transient faults, but they tend to be less significant

Physical Defects: Manufacturing Defects

- Manufacturing is not a perfect process, especially for microprocessors
  - It's not easy to manufacture something with dimensions on the order of 10nm
  - Many stages of chip processing which have to be done perfectly and avoid contamination
- And testing doesn’t filter out all defective systems
  - Often impossible to test for every possible defect in a reasonable amount of time
  - Also, testing won’t detect defects that don’t manifest immediately
- Nanotechnology makes this problem even worse
Evidence of Manufacturing Defects

- Void under anchor
- Silicon damage
- Metal2 extrusion/ILD2 crack
- Metal 1 Shelving
- M4-M4 Short
- Poly stringer
- M4 Void Formations

Physical Defects: Manufacturing Defects

- Manufacturing flaws
  - Bad solder connection between chip and board
  - VLSI defects
- Trends:
  - Flaws may decrease as manufacturing process matures
  - But flaws increase at start of each new process
  - Tougher to avoid VLSI defects as dimensions shrink
Physical Defects: Manufacturing Defects

- VLSI fabrication process variability
  - During fab, there’s some amount of variability in dimensions
    - Thickness of gate oxide dielectric
    - Length of channel
    - Area of via

- Variability can lead to undesirable behavior
  - Gate thickness falls below usable threshold $\rightarrow$ extra leakage current
  - Wire resistance is too high $\rightarrow$ signal too slow for clock

- Trend: variability rising as VLSI dimensions shrink
  - When dimensions are on the order of a handful of atoms, it doesn’t take much variability to cause significant problems

Physical Defects: Operational Defects

- Permanent (hard) defects can occur during operation

- Electromigration
  - Movement of metal atoms due to electron flow and temperature
    - Increases with current density and temperature
    - Unidirectional current: Power rails
  - Trend: getting worse as wires become smaller and chips become hotter
Physical Defects: Operational Defects

- Time Dependent Dielectric Breakdown (TDDB)
  - MOSFET transistor has a gate oxide that insulates the gate from the channel
  - If this oxide breaks down, will get a short between gate and channel
  - Trend: getting worse as gate oxides become thinner (only a handful of atoms thick!)

- Transistor aging
  - Causes
    - Negative and Positive Bias Temperature Instability (NBTI and PBTI)
    - Hot Carrier Injection (HCI)
  - Effects:
    - Change of transistor’s threshold voltage over time → Reduced current → Transistors become slower → cause timing failures
  - Trend: getting worse with technology scaling
Impact of aging on delay

Hardware Design Flaws: Logical Bugs

- Famous examples:
  - Intel Pentium floating point divide didn’t work in every single case due to bug in design
    - very costly recall
  - Sun UltraSPARC III had design flaw in a special cache that meant that it couldn’t be used
    - loss in performance
  - AMD’s quad-core Barcelona chip had design bug in TLB hardware
    - Long, expensive delay in shipping chips
Hardware Design Flaws: Timing Bugs

- Logic is fine, but the timing analysis is flawed
- Example: clocking a processor at 4 GHz when there's a slow path in the pipeline that can only run at 3.8 GHz
- Timing analysis must consider critical path delay and environmental effects (operating temperature, EMI, cross-talk, etc.) to determine the maximum operating speed
- This problem is exacerbated by process variability

Design Flaws: Software

- We all know that software has bugs
- Types of bugs
  - Incorrect algorithm
  - Memory leak (C, C++, but not Java)
    - Allocating memory, but not deallocating it
  - Reference to NULL pointer (C, C++, but not Java)
    - This usually leads to a seg fault and core dump
  - Incorrect synchronization in multithreaded code
  - Allowing more than 1 thread in critical section at a time
Operator Error

- It has been argued that operator error is the leading cause of computer system failures
- Examples
  - `rm -R *` (in the wrong directory)
  - Incorrect installation of software
  - Frying a board when installing new memory chips
  - Dropping the laptop (and/or kicking it)

Purpose of Fault Modeling

- Model = abstraction of physical phenomenon
- Simple, tractable way to analyze effects of faults
- Limitations
  - Model multiple defects (loss of resolution)
  - May not distinguish defects or miss defects
  - May not be realistic
Fault Modeling: Example

- “fail-stop” network switch
  - if a fault occurs, the switch will just stop doing anything
- Model reflects the behavior of many potential underlying faults
  - E.g., switch has short from power to ground, switch is on fire, etc.
- Easier to work with this model than to consider all possible faults
- Fail-stop fault model for network switch doesn’t handle case where switch starts routing packets incorrectly
  - And this fault model represents several realistic underlying faults

Fault Models for Digital Circuits

- Traditional fault models
  - Stuck-at faults
    - A line is always at a fixed value (1 or 0)
  - Bridges
    - Lines shorted together
    - Z(X,Y): modeled as OR, AND
  - Transition delay faults
    - Transition arrives too late
    - Slow-to-rise, slow-to-fall
- Fault models for nano-scale circuits
  - Crosstalk, small/path delay faults, resistive opens and bridges
How Many Faults at Once?

- Many fault models include the assumption that only one fault can occur at a given instance
  - Helps to make analysis more tractable
  - E.g., “single stuck-at fault” model
- Reasonable assumption if:
  - Faults are rare
  - System doesn’t require extreme reliability
  - Faults are detected and, if necessary, removed quickly
- The problem with latent faults
  - Fault occurs, but isn’t detected
  - Later, a “single” fault occurs, but this is now a double fault scenario
  - If you only plan for single faults, then this situation is a problem
Software Fault Models

- **Allocation management**: Memory region used after deallocation
- **Copying overrun**: Program copies data past end of a buffer
- **Pointer management**: Variable containing data address corrupted
- **Wrong algorithm**: Program works executes but uses wrong algorithm
- **Uninitialized variable**: Variable used before initialization
- **Undefined state**: System goes into unanticipated state
- **Data error**: Program produces or reads wrong data
- **Statement logic**: Statements executed in wrong order or omitted
- **Interface error**: A module’s interface incorrectly defined or incorrectly used
- **Memory leak**: Program does not deallocate memory it has allocated
- **Synchronization**: Error in locking or synchronization code

Software Fault Models

- **Incorrect computation**: Arithmetic overflow or an incorrect arithmetic function
- **Data fault**: Incorrect constant or variable
- **Data definition fault**: Fault in declaring data or data structure
- **Missing operation**: Omission of a few lines of source code
- **Side effect of code update**: Not all dependencies between software modules considered when updating software
- **Unexpected situation**: Not providing routines to handle rare but legitimate operational scenarios
